How does the population growth vary if it starts from a small initial value (N 0 = 5 individuals) versus a larger initial value (N 0 = 100 individuals)? When the population starts at a small value, the initial population growth rate is slow, with an almost zero slope. Gradually, this rate increases and curves upward more rapidly.

Population Dynamics. Population dynamics is the study of the size and age composition of populations. This simulation produces data for population size over time for three different species in a simple food chain; a plant, a herbivore, and a predator. The starting populations, as well as the reproductive rates and the amount of food needed by the herbivore and predator, can be controlled by the user.

Population dynamics is the branch of life sciences that studies the size and age composition of populations as dynamical systems, and the biological and environmental processes driving them (such as birth and death rates, and by immigration and emigration). Example scenarios are ageing populations, population growth, or population decline.

Abiotic and biotic factors can affect the growth and death rates of a population, so these fluctuations also require consideration when modeling a population's change over time. Sometimes, scientists need to consider how reproductive strategies play a part into the dynamics of a population over time.
